

LeeSide Rename Plan

UpLift → LeeSide · GitHub Pages path change · Prepared for a fresh chat

Before you start

- 1. Back up your data first.** Settings → Export backup (JSON). This is independent of everything below — verified directly in the app's own code, the backup file contains no path or URL references at all.
- 2. Do this on WiFi, not cellular.** Data Saver restricts photo syncing on cellular specifically — WiFi means a clean, complete pull of everything (photos included) once you sign back in at the new URL.

The sequence — order matters

- 1. You** rename the repo on GitHub (Settings → repository name).
- 2. Claude** updates every code-side reference to the old path (full list below).
- 3. You** deploy the updated files.
- 4. You** (and your one existing tester) delete the old home-screen shortcut and reinstall from the new URL.
- 5. You** sign in again at the new URL and confirm your data — flights, notes, photos — comes back correctly.

This order avoids any window where the app is live but pointing at a URL that doesn't exist yet — the repo needs to actually be renamed before the code can correctly point at the new path.

What needs to change

File	What changes	Count
<code>index389.html</code>	Guide link (×3), privacy policy link, and the service worker's own registration path (<code>/UpLift/sw.js</code> → <code>/LeeSide/sw.js</code>)	5
<code>uplift-guide.html</code>	Two text mentions of the old URL (footer, opening instructions)	2
<code>install.html</code>	The "open the app" link	1
PDF build script	Same app link, inside the install-guide PDF generator	1
<code>sw.js</code>	App shell URL list, the guide-caching path check, and the screenshots-caching path check — see detail below	3 spots 4 strings

sw.js — the three exact spots

```
const URLS=['/UpLift/', '/UpLift/index.html'];
```

The app shell list itself — if this isn't updated, the service worker caches and matches against a path that no longer exists, breaking offline-first entirely.

```
isGuideHtml = url.pathname==='UpLift/uplift-guide.html'  
isScreenshot = url.pathname.startsWith('/UpLift/screenshots/')
```

Both would silently stop matching under the new path — not an obvious error, just quietly falls back to default behavior. Exactly the kind of thing worth catching now rather than discovering offline at a hill.

What does NOT need to change

- **manifest.json** — already uses relative paths (`start_url: ".", scope: "."`) and relative icon references. Confirmed by reading the actual file. Zero edits needed.
- **IndexedDB names** (`uplift_db`, `uplift_data`) — a separate, unrelated concern (storage keys, not hosting path). Untouched by this rename in either direction.
- **Google Drive backup filename** — same reasoning, completely independent of where the app is hosted.
- **Google sign-in** — confirmed directly against Google's own developer docs: "JavaScript origins cannot contain the path component." Your OAuth is tied to `chnevill.github.io` as a whole, not `/UpLift/` specifically.

The one real risk to know about

Confirmed via GitHub's own documentation: renaming a repo automatically redirects almost everything — issues, git operations, the repo page itself — **except GitHub Pages URLs specifically**. That's the one exception GitHub calls out by name. So the old URL won't softly redirect after the rename — it will simply stop resolving, right as the new one becomes live. This is exactly why the sequence above puts the repo rename first: there should be no moment where deployed code points at a path that doesn't exist yet.

Data safety, in plain terms

Verified directly in the app's own code, not assumed: your flight/note/gear data *and* your actual photos both sync to your own Google Drive — photos travel as their own separate small files specifically so the main sync stays light. Regular browser storage (IndexedDB) is scoped to the origin as a whole, not the path, so it should be unaffected technically either way. The one place I'm genuinely less certain is the installed home-screen app specifically, moving from one install to a freshly-scoped one — but it doesn't actually matter: even in the worst case, signing back in at the new URL pulls everything back down from Drive, the same way any normal sign-in already does.

After the rename

- Delete the old home-screen shortcut on your own device(s), reinstall from the new URL.
- Do the same for your one existing tester — send them the new link directly.
- Sign in fresh at the new URL and confirm flights, notes, and photos all came back correctly before considering this done.
